ON THE COVER

Diversification of MADS box genes has been proposed as a major driving force for floral diversity in land plants. Yamaguchi et al. (pages 15–28) investigate the functions of rice OSMADS3 and OSMADS58, homologs of Arabidopsis AGAMOUS, a C-class MADS box gene that regulates stamen and carpel identity and floral meristem determinacy. The authors show that disruption of OSMADS3 in a T-DNA insertion line results in homeotic transformation of stamens into lodicules and the ectopic development of lodicules in the second whorl. By contrast, RNA-silenced lines of OSMADS8 developed flowers that reiterate lodicules, stamens, and carpel-like organs, suggesting loss of determinacy in the floral meristem. The results suggest that functions regulated by AGAMOUS in Arabidopsis have been partially sub-functionalized during the evolution of rice into two paralogous genes, OSMADS3 and OSMADS58, which arose from a recent gene duplication event. In addition, the development of ectopic lodicules in OSMADS3 loss-of-function mutants points to a role for C-class genes in the asymmetric distribution of lodicules in the rice flower.
